ABSTRACT

This report documents the results of tests performed on end-over-end wire rope loops made from 3/8, 1/2, and 5/8 inch independent wire rope core (IWRC) and fiber core wire ropes. The tests were performed during September, October, and November 1978 to study the holding power of wire rope clips in a connection of a wire rope loop.

I. EXECUTIVE SUMMARY

1. SCOPE. This report presents the results of tests performed on 3/8, 1/2, and 5/8 inch independent wire rope core (IWRC) wire rope, and 3/8, 1/2, and 5/8 inch fiber core wire rope. The test samples consisted of end-over-end wire rope loops held together with various numbers of clips.

2. OBJECTIVE. To study the holding power of wire rope clips in a connection of a wire rope loop when the torque on the nuts of the clips is varied.

3. APPROACH. A 50,000 pound capacity tension tester was used to apply forces to a loop of wire rope that was affixed between a stake pocket and a shackle. The tension tester was used to apply a force to the wire rope loop until a predetermined displacement occurred between the wire ropes at the connection or until the wire rope broke.

Instrumentation was used to measure the force into the wire rope loop, displacement between the wire ropes at the connection, and the displacement between the platens on the tester.

4. RESULTS. A small displacement between wire ropes in a connection utilizing Type I wire rope clips does not indicate that the connection has been subjected to its maximum holding force.

Used clips are less effective than new clips.

These laboratory tests show the difficulty that was encountered in obtaining repeatable force vs torque data for wire rope loops.

5. CONCLUSIONS. The maximum holding power of wire rope clips depends upon several factors. Some of these factors are: (1) torque on the nuts of

the clips, (2) alignment of the U-bolt with the base of the clip, (3) displacement of the wire ropes in the connection - the larger the wire rope size, the larger the displacement of the ropes in the junction before the maximum force is reached, (4) the use of new clips, and (5) adequate length of dead end from the clips.

II. INTRODUCTION

To ship cargo by the rail mode of transportation, the freight must be secured in accordance with rules established by the Association of American Railroads (AAR). To demonstrate compliance with those rules the government performs a rail impact test on the item and the proposed restraint system. The test subjects the item and restraint system to shocks produced by a railroad car impacting another railroad car, or cars, at speeds up to eight miles per hour.

One component of a restraint system that is used to secure items, such as wheeled vehicles, on a flatcar is wire rope. Wire rope clips are used to maintain a configuration of the wire rope during shipment of the cargo. Specifications for some of the rail impact tests required that the clips be tightened to such a high torque that the wire rope broke before slipping when it was subjected to shocks of an 8 MPH rail impact.

If a wire rope in a restraint system breaks between origin and destination of the cargo, the probability of an accident is increased by a large percentage. To reduce this probability the wire rope should slip at the clip connection when a force equal to the breaking strength of the wire rope is applied to the configuration.

This report presents the results of laboratory tests performed on 3/8 inch, 1/2 inch, and 5/8 inch wire rope. The testing was conducted during September, October, and November 1978.

III. DESCRIPTION OF TEST MATERIALS AND EQUIPMENT

The material specifications for the wire rope are: steel wire, plain, pre-formed, regular lay, Mac Whyte Wire Rope Co. (or equal), refer to Federal Specification RR-W-410, with a nominal breaking strength as shown below. A section of IWRC rope is shown in Figure 1.

SIZE INCHES	NOMINAL BREAKING STRENGTH, POUNDS	
	INDEPENDENT WIRE ROPE CENTER (IWRC)	FIBER CORE
3/8	13,120	12,200
1/2	23,000	21,400
5/8	35,800	33,400

Thimbles were standard, Type II in accordance with Federal Specification FF-T-276.

Purchase description of the clips was: clips ("U" bolt, Crosby, heavy duty, or equal), reference Federal Specification FF-C-45D, Type I, Class I.

A compression-tension tester was used to apply the forces to each loop of wire rope, refer to Figure 2. Also shown in Figure 2 is a test set-up for a loop of wire rope and the instrumentation that was used to measure the force and displacements. Closer views of the instrumentation are shown in Figures 3 and 4.

Specifications for the test equipment are shown in Table 1. A schematic of the equipment that was used to record the raw data is shown in Figure 5.

IV. TEST PROCEDURE

A typical test set-up of the materials and equipment is shown in Figure 3. The nuts on the clip installed on the bottom dead end of the wire rope loop are tightened with no specific torque specified. The other clips were tightened to a designated torque.

All of the instruments were calibrated prior to each test. The displacement gage between the top and bottom platens of the tester was calibrated with 200 pound force on the wire rope loop.

During conduct of the test the force was increased until the instrumentation showed displacement of the wire rope at the connection point. Displacement is defined as the relative movement of a point on one wire rope in the connection compared to an adjacent point on the other rope in the connection. To account for stretch and slack in the rope between the clips and between the clips and the displacement gage, the allowable displacement varied between tests and within a test. The variance was necessary because at the beginning of the tests it was assumed that any displacement in the connection would be an indication that the connection had been subjected to its maximum holding force. However, the first tests on the 1/2 and 5/8 inch wire rope samples produced results that showed displacement could not be used as a criteria for failure. Therefore, for most of the tests on the 1/2 and 5/8 inch wire rope loops the first application of the force was increased until the displacement gage indicated 1/4 inch. Additional force applications on the same wire rope loop were stopped at an allowable displacement of 1/8 inch. When the amount of predetermined displacement is reached, the force is decreased immediately to approximately 2,000 pounds.

This procedure was used to reduce the total displacement and also to provide a safe environment while the clips are being tightened to the next designated torque.

V. RESULTS AND DISCUSSION

Results from the laboratory tests are shown in Tables A-1 through A-6. Data from these tables were used to show the relationship between the force on the wire rope loop and the torque applied to the clips (see Figures 6 through 11).

Observations of the laboratory tests result in several comments that can be made about wire rope loops held together with wire rope clips.

1. The strands of wire in a regular lay wire rope are aligned almost parallel with the direction of the wire rope. This alignment allows the wire rope to form grooves into the clips rather than to scrape metal from the clips. Note the grooves in the clips shown in Figure 12.

2. The dead end of a wire rope loop should be of sufficient length to prevent unraveling. The wire rope clips that were installed near an unraveled end required a larger number of turns on the nuts to achieve the designated torque when compared to other test samples that had adequate dead ends. This requirement suggests that the clip would lose some of its holding power because of the unraveling. A taped end will require a longer length than a wired end. A 3 to 4 inch taped end is not a sufficient length.

3. A small displacement between wire ropes in a connection is not an indication that the connection has been subjected to its maximum holding force. A 5/8 inch wire rope connection can withstand a displacement of more than one inch before the maximum force is reached (refer to Table A-3). Some of the displacement is attributed to the U-bolt of the clip moving to obtain a good "binding like" alignment with the base of the clip and the two wire ropes in the connection.

FIGURE 11. Results from Laboratory Tests on Loop of 5/8-Inch Fiber Core Wire Rope.

11-078-1234/DARCOM 78 DARCOM AMMUNITION CENTER - SAVANNA, ILLINOIS

Figure 12. Comparison of used clips.

4. Low torques, such as 10 and 15 ft-lbs, are time consuming to apply to 3/8 inch or larger clips. When the nut on one side of the clip is tightened to the designated torque the nut on the other end of the U-bolt will require retightening. This comment takes into consideration the proper procedure for tightening the nuts - the torque on each nut is increased on an alternate basis.

5. When the dead end of a wire rope connection is used to indicate displacement, the elasticity of the wire rope must be taken into consideration. Observe the location of the displacement gage in Figure 4. Since the dead end of the connection will not stretch and the adjacent live rope would stretch when a force is applied to the loop, there could be a false indication of a displacement in the connection.

Post test analysis suggests that each test loop should be subjected to an increasing tensional force until failure or excessive slippage occurs. For this procedure the displacement of the wire ropes in the connection would not be used as a criteria for failure for the designated torque. However, we do not feel that the possibility of error in the measurement of displacements for these tests nullifies the conclusions since the conclusions are based on trends in the data rather than absolute values.

6. A comparison of data in Table A-3 (for torques applied to four clips) from runs 4, 8, and 9 against data from runs 5 and 10 shows the decreased efficiency of used clips. In runs 5 and 10 (using new clips), the capacity of the test equipment was reached without excessive slippage. In runs 4, 8, and 9 (using clips from prior runs) excessive slippage was noted prior to reaching the capacity of the test equipment.
